Methods

Descriptive Statistics

The analyzed set of data consists of 23 variables and a total number of $N = 515$ participants. Values for each variable range from 0 (“extremely uncharacteristic for myself”) to 4 (“extremely characteristic of myself”). No data is missing, as all items have been answered by all subjects. The distribution of each variable was observed with focus on skewness and kurtosis, to examine the normality of the data. Across all variables, the skewness ranged from -0.753 to 1.064 whereas the kurtosis ranged from -1.047 to $.866$. According to the recommendations by Fabrigar et al. (1999), these values indicate a near enough approximation of normality to conduct an EFA (skewness $< +2$; kurtosis $< +7$). However, 3 variables (“Generally, I am not very aware of myself”, “It’s hard for me to work when someone is watching me”, “I never take a hard look at myself”) were excluded following the recommendation of Field (2017) to exclude items that have no correlation of $>.3$ with any other variable. Therefore, 20 of 23 variables were included in the analysis without transformations. The subject to variable ratio equals 25.75 subjects per variable.

Exploratory Factor Analysis

In lack of a specific theory or hypothesis regarding the structure within the analysed data, an exploratory factor analysis (EFA) was performed to investigate its underlying factor structure. The EFA was based on the correlation matrix of the 20 included variables (see app. 3). To test the appropriateness of an EFA based on this matrix, Bartlett’s test was performed and KMO of sampling adequacy was computed. Bartlett’s test $X^2(190) = 3039$, $p < .001$ was statistically significant, indicating a sufficient correlation of items, whereas $KMO = 0.835$ indicates a sufficient (“meritorious”) sampling adequacy according to Kaiser (1974). The determinant of the correlation matrix is $>.002$, which lies above the threshold of $>.00001$ suggested by Fields (2017), indicates an acceptable collinearity. As a method for factor structure, principal axis factoring was used. The chosen rotation method was “direct oblimin” ($\delta = 0$), to allow factors to correlate as recommended by Fabrigar et al. (1999) as a first analysis.

Selection of Number of Factors

Multiple criteria were used to assess the number of factors. No theory-based number of expected factors existed. According to Kaiser’s criterium, which includes factors with an

eigenvalue >1 , a number of 5 factors were to be selected. A subjective assessment of a screeplot (see app. 4) resulted in a number of 4 or 5 factors to exclude. A parallel analysis based on simulated data using a web-based parallel analysis engine (Patil et al., 2017) resulted in a number of 4 factors, whose eigenvalues were higher or equal to their randomly generated equivalents (see app. 5). Given these results, the low number of 20 variables and the fact that the fifth factor barely passes Kaiser's criterium with an eigenvalue of 1.02, the fifth factor was excluded from the analysis. Thus, a 4-factor solution was adopted.

Results

Factor Structure

The four extracted factors explain a total variance of 41.25%. The initial eigenvalues and the variance explained by each factor after rotation are shown in table 1.

Table 1.

Eigenvalues and variance explained by factors.

Factor	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	4.754	23.768	23.768	4.191	20.957	20.957
2	2.754	13.769	37.537	2.234	11.172	32.129
3	1.773	8.866	46.403	1.214	6.071	38.200
4	1.250	6.251	52.654	.610	3.049	41.249

The correlations between factors are shown in table 2. The values of the correlation coefficients clearly indicate that the factors have a small to medium correlation. Thus, an oblique rotation as has been applied is a proper solution for the analyzed dataset. All factors are correlated positively.

Table 2.

Factor correlation matrix.

Factor	1	2	3	4
1	1.000	.119	.253	.410
2	.119	1.000	.119	.009
3	.253	.119	1.000	.359
4	.410	.009	.359	1.000

Table 3 shows the loadings in the pattern matrix of the items on the extracted factors with an applied threshold of 0.4 to cut off small factor loadings (for a complete pattern matrix see app). As we can see, 6 items load on factor 1, 5 items on factor 2, 3 on factor 3 and 5 on factor 5. Two items have no loadings $>.40$ on any of the extracted factors. Each variable (with exception of those that have no loadings $>.40$) unambiguously loads on only one factor with $>.40$, which results in a clear simple structure.

Table 3.

Pattern matrix.

	Factor			
	1	2	3	4
I'm self-conscious about the way I look	.779			
I'm usually aware of my appearance	.721			
Before I leave my house, I check how I look	.663			
I'm concerned about what other people think of me	.481			
I usually worry about making a good impression	.455			
I care a lot about how I present myself to others	.442			
It takes me time to get over my shyness in new situations		.761		
I feel nervous when I speak in front of a group		.726		
Large groups make me nervous		.711		
I get embarrassed very easily		.637		
It's easy for me to talk to strangers		.493		
I think about myself a lot			.667	
I'm always trying to figure myself out			.531	
I often daydream about myself			.528	
I sometimes step back (in my mind) in order to examine myself from a distance				
I'm quick to notice changes in my mood				.592
I'm constantly thinking about my reasons for doing things				.483
I know the way my mind works when I work through a problem				.472
I generally pay attention to my inner feelings				.420
I'm concerned about my style of doing things				

In the appendix, the factor structure matrix (app. 6) and the pattern matrix including all loadings (app. 7) is added. Also, a table depicting the communalities of each variable is attached (app. 8).

Internal Reliability of Factors

For each factor, Cronbach's alpha was computed to assess the internal reliability of the extracted factors. Only variables with a loading of $>.40$ were included in the analysis.

Table 4.

Internal reliability of factors.

Factor	Number of Items	Cronbach's alpha
1	6	.801
2	5	.794
3	3	.661
4	4	.648

Naming of Factors

A qualitative naming and description of the factors should be attempted in this section. Variables with high loadings on factor 1 specifically address how much a person cares about how others perceive him or her in terms of looks, appearance and impression. Therefore, a label such as "caring about impression of others" could be applied. Variables that load on factor 2 address shyness and nervousness, thus "timidity" is an appropriate label. Variables loading on factor 3 address self-referential thinking, dreaming and perception, labelled as "self-referential cognition". Variables loading on factor 4 mainly address the detection of inner emotional states, motivations and cognitive processes, of which "awareness of inner states" might be an appropriate label.

Table 5.

Factor labels.

Factor	Label
1	Caring about impressions of others
2	Timidity
3	Self-referential cognition
4	Awareness of inner states

Internal Replicability

An analysis of internal replicability was performed as described in Osborne & Fitzpatrick (2012). For this purpose, the sample was randomly divided into two smaller samples of $N=258$ and $N=257$ subjects. In these subsamples, after excluding the same variables as in the whole sample (due to the same criterium), the same factor analysis was performed (principal axis factoring, direct oblimin rotation, set number of four factors, loading cut-off value of .40). In the first subsample, the factor structure resembles the one of the large sample (see appendix 9 for the pattern matrix). The factors are highly similar, even though factors 3 and 4 are reversed. Also, the order of variables ranked by factor loadings varies slightly, while factor 4 consists only of variables that load negatively. However, the second subsample displayed a highly different factor structure (see appendix 10). Here, factor 1 of the other samples is divided into two separate factors (factor 1 and 4), whereas a number of variables loading on factor 3 and 4 of the other samples form a combined factor. Only factor 2 resembles the corresponding factors in the other samples. As suggested by Osborne & Fitzgerald (2012), a table which displays all factor loadings across both subsamples is added in the appendix (app. 11).

Conclusion & Discussion

In this record, an exploratory factor analysis was performed on a set of data including 23 variables. After the exclusion of 3 items, a factor analysis based on principal axis factoring and oblique rotation (direct oblimin) resulted in an extraction of four latent factors, that account for 18 of the included variables. These factors have small to medium intercorrelations, which justifies the application of an oblique rotation method. Especially factors 1 (“caring about impression of others”) and 4 (“awareness of inner states”) have a medium correlation of $r = .410$. The internal reliability of all factors is Cronbach’s $\alpha > .6$, which can be considered as sufficient. Especially factors 1 and 2, labelled as “caring about impression of others” and “timidity”, have a high internal reliability around 0.8, while factors 3 (“self-referential cognition”) and 4 (“awareness of inner states”) exhibit a lower internal reliability (see table 4). However, an analysis of internal replicability, in which the same analysis was independently performed on two distinct subsamples randomly sampled from the data, revealed problems in structural replicability. Anyways, these differing factor structures should be interpreted with caution, as the error rate increases strongly with the lower number of answers per item (Osborne, 2014, p.49). Also, the factor structure presented in the main analysis makes substantially sense in terms of groupings of items and common labels. To further investigate

this issue, the same procedure could be repeated several times to identify and revise problematic items. Also, a follow-up study with a large and independent sample should be conducted, to further investigate the underlying factor structure of the set of variables with another EFA or by performing a confirmatory factor analysis (CFA) based on the exploratory analysis presented in this record. For this purpose, the three items that have been excluded from this analysis due to lack of correlation with other variables should also be revised.
